

Kaa IoT Platform Home

Welcome to the Kaa project wiki!

GET STARTED NOW >

or hang on for a while and take a swift tour through key Kaa features.

Kaa in a nutshell

Kaa is a highly flexible open-source platform for building, managing, and integrating applications in the Internet of Things. Kaa offers a holistic approach for implementing rich communication, control, and interoperation capabilities into connected products and smart devices. On top of this, powerful back-end functionality of Kaa greatly speeds up IoT product development, allowing vendors to concentrate on maximizing their product's unique value to the consumer.

Kaa IoT platform is comprised of the server component and the endpoint SDK that is integrated into client applications. For more information on the Kaa server architecture, please refer to the [Design reference](#).

Key features of Kaa are:

- **Events:** Kaa provides a mechanism for delivery of configurable event messages across connected devices. Events may be set as either unicast, that is transmitted to a single recipient, or multicast, that is transmitted to several recipients. For detailed information on managing events, refer to the [Events](#) section.
- **Data collection:** Kaa endpoints perform temporary storage of data records ("logs") of any predefined structure. Kaa endpoint SDK implements log upload triggers that initiate periodic logs upload from the endpoint to the server. The server can store logs into the filesystem, big data platforms like Hadoop, MongoDB, etc., or submit the data directly to the stream analytics processors. For example, logs can be used to help debug client applications, analyze user behavior, identify anomalies, etc. For detailed information on log management, refer to the [Logging](#) section.
- **Profiling and grouping:** Kaa introduces the concept of the endpoint profile, which is a set of data that the client exposes for the access by Kaa applications. Profiles can then be used to organize the endpoints into groups. Endpoint groups can be used, for example, to send targeted notifications or adjust software behavior. For detailed information on profiles, filtering, and grouping, refer to the [Endpoint profiling](#) and [Endpoint grouping](#) sections.
- **Notifications delivery:** Kaa features a topic-based notification system that allows the server to deliver messages of any predefined structure to subscribed endpoints. The notification topic access is granted via the endpoint's group membership. For detailed information about managing notifications, please refer to the [Notifications](#) section.
- **Data distribution:** Kaa allows performing updates of operational data, such as configuration data, from the Kaa server to endpoints. This feature can be used for centralized configuration management, content distribution, etc. Using Kaa's data schemas, developers are able to define any type of data structure and constraint data types. For detailed information on data distribution, refer to the [Configuration](#) section.
- **Transport abstraction:** Kaa's data channel abstraction architecture presents software vendors with freedom in selecting a networking stack for establishing communication between the server and endpoints - WiFi, Ethernet, Zigbee, mqtt, CoAP, XMPP, TCP, HTTP, etc. A prominent characteristic of Kaa is its ability to build applications that function over any type of network connection and communicate with devices even over intermittent data connections.
- **Support of multi-tenancy and multi-application configuration:** The Kaa server is able to serve multiple business entities and multiple applications independently on a single server instance. For more details, refer to the [Design reference](#).

Supported platforms

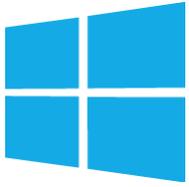

Click an icon to jump into integrating Kaa with the specific operating system or hardware platform.

Operating systems

Linux

Hardware platforms

beaglebone

RaspberryPi
